Problem Statement

Solve the differential equation $\frac{d^2y}{dx^2} + 1 = 0$ with initial conditions $y(0) = 0$ and $y'(0) = 0$

Input Parameters

Variable	Description
c_1	First Integration constant
c_2	Second Integration constant
n	Order of given differential equation
a_i	Coeefficient of ith derivative of the function in the equation
c	constant in the equation
y^i	ith derivative of given function
$\mathbf{y}(t)$	$\begin{pmatrix} c \\ y(t) \\ y'(t) \\ \vdots \\ y^{n-1}(t) \end{pmatrix}$
h	stepsize, taken to be 0.001
$u(x)$	Unit step function

Laplace Transform properties

Properties of Laplace tranform

$$\mathcal{L}\left(y''\right) = s^2\mathcal{L}\left(y\right) - sy\left(0\right) - y'\left(0\right) \tag{3.1}$$

$$\mathcal{L}\left(1\right) = \frac{1}{s} \tag{3.2}$$

$$\mathcal{L}^{-1}\left(\frac{2}{s^3}\right) = x^2 u\left(x\right) \tag{3.3}$$

$$\mathcal{L}\left(cf\left(t\right)\right) = c\mathcal{L}\left(f\left(t\right)\right) \tag{3.4}$$

Equation solving

Applying the properties to the given equation

$$y'' + 1 = 0 \tag{3.5}$$

$$\mathcal{L}\left(y''\right) + \mathcal{L}\left(1\right) = 0 \tag{3.6}$$

$$s^2\mathcal{L}\left(y\right) - sy\left(0\right) - y'\left(0\right) + \frac{1}{s} = 0 \tag{3.7}$$

$$\tag{3.8}$$

Substituting the initial conditions gives

$$s^3\mathcal{L}\left(y\right) + 1 = 0 \tag{3.9}$$

$$\mathcal{L}\left(y\right) = \frac{-1}{s^3} \tag{3.10}$$

$$y = \frac{-1}{2}\mathcal{L}^{-1}\left(\frac{2}{s^3}\right) \tag{3.11}$$

$$y = \frac{-1}{2}x^2u\left(x\right) \tag{3.12}$$

The theoritical solution is

$$f(x) = \frac{-x^2}{2} u(x) \tag{3.13}$$

Computational Solution

Consider the given linear differential equation

$$a_n y^n + a_{n-1} y^{n-1} + \cdots + a_1 y' + a_0 y + c = 0 \tag{3.14}$$

Then

$$y'(t) = \lim_{h \to 0} \frac{y(t+h) - y(t)}{h} \tag{3.15}$$

$$y(t+h) = y(t) + h y'(t) \tag{3.16}$$

Similarly

$$y^i(t+h) = y^i(t) + h y^{i+1}(t) \tag{3.17}$$

$$y^{n-1}(t+h) = y^{n-1}(t) + h y^n(t) \tag{3.18}$$

$$y^{n-1}(t+h) = y^{n-1}(t) + h\left(-\frac{a_{n-1}}{a_n} y^{n-1} - \frac{a_{n-2}}{a_n} y^{n-2} - \cdots - \frac{a_0}{a_n} y - \frac{c}{a_n}\right) \tag{3.19}$$

Where i ranges from 0 to $n-1$

$$\mathbf{y}(t+h) = \mathbf{y}(t) + \begin{pmatrix} 0 & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 1 & 0 & \dots & 0 & 0 \\ 0 & 0 & 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 0 & 1 \\ -\frac{1}{a_n} & -\frac{a_0}{a_n} & -\frac{a_1}{a_n} & -\frac{a_2}{a_n} & \dots & -\frac{a_{n-2}}{a_n} & -\frac{a_{n-1}}{a_n} \end{pmatrix} (h\mathbf{y}(t)) \tag{3.20}$$

$$\mathbf{y}(t+h) = \begin{pmatrix} 1 & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & h & 0 & \dots & 0 & 0 \\ 0 & 0 & 1 & h & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 1 & h \\ -\frac{h}{a_n} & -\frac{a_0 h}{a_n} & -\frac{a_1 h}{a_n} & -\frac{a_2 h}{a_n} & \dots & -\frac{a_{n-2} h}{a_n} & 1 - \frac{a_{n-1} h}{a_n} \end{pmatrix} (\mathbf{y}(t)) \tag{3.21}$$

Discretizing the steps gives us

$$\mathbf{y}_{k+1} = \begin{pmatrix} 1 & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & h & 0 & \dots & 0 & 0 \\ 0 & 0 & 1 & h & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 1 & h \\ -\frac{h}{a_n} & -\frac{a_0 h}{a_n} & -\frac{a_1 h}{a_n} & -\frac{a_2 h}{a_n} & \dots & -\frac{a_{n-2} h}{a_n} & 1 - \frac{a_{n-1} h}{a_n} \end{pmatrix} (\mathbf{y}_k) \tag{3.22}$$

where k ranges from 0 to number of data points with y_0^i being the given initial condition and vector $\mathbf{y}_0 = \begin{pmatrix} c \\ y(0) \\ y'(0) \\ \vdots \\ y^{n-1}(0) \end{pmatrix}$

For the given question

$$\mathbf{y}_{k+1} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & h \\ -h & 0 & 1 \end{pmatrix} \mathbf{y}_k \tag{3.23}$$

Record the y_k for

$$x_k = lowerbound + kh \tag{3.24}$$

and then plot the graph. The result will be as given below.
The codes below verifies the obtained solution.

Plot of the function

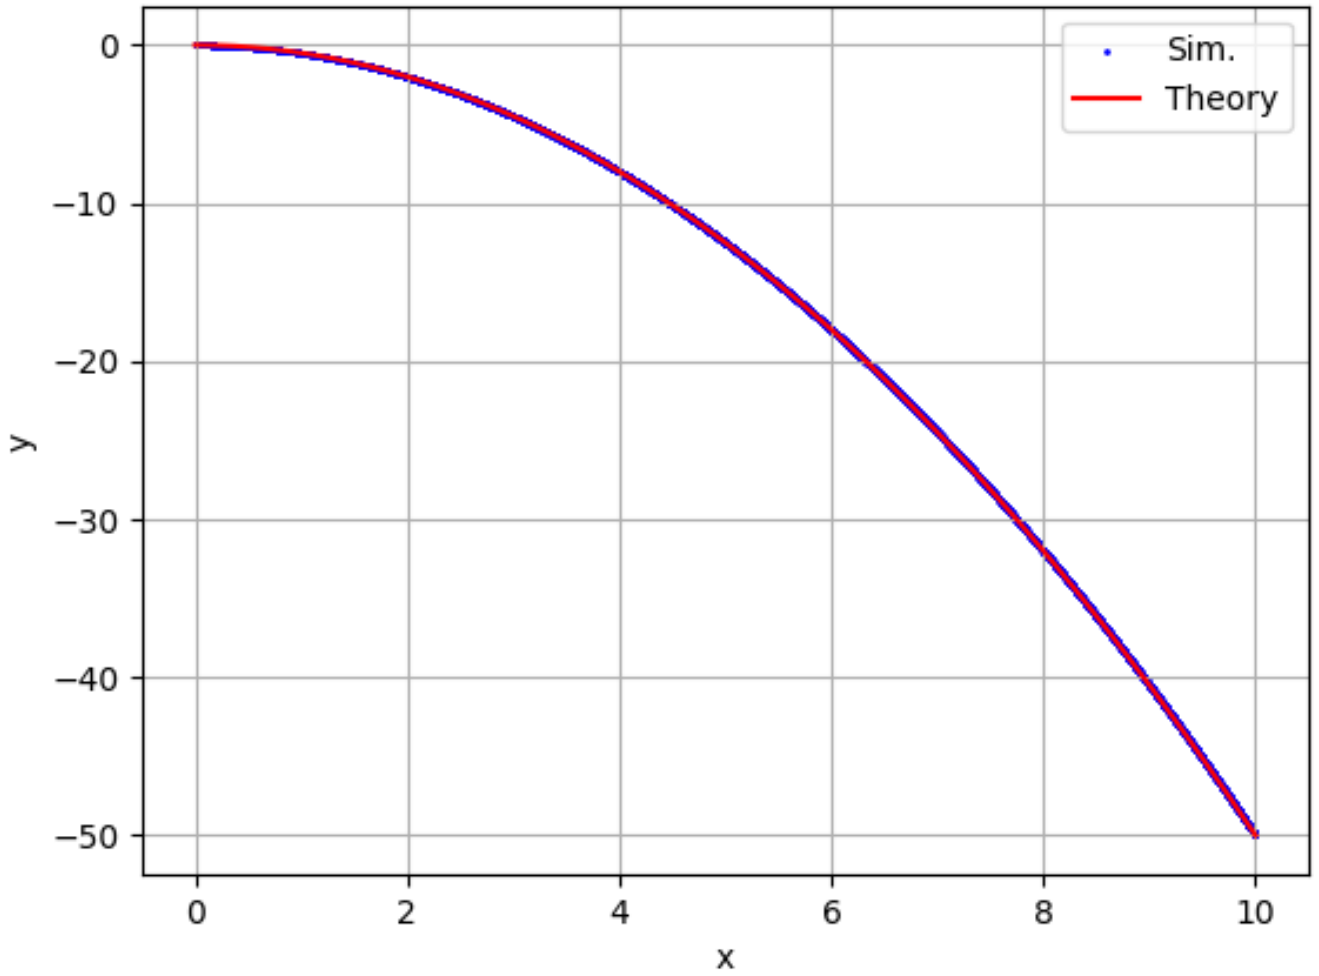

Figure: Function satisfying given differential equation

C Code

```
#include <stdio.h>
#include <stdlib.h>
#include <math.h>
#include "functions.h"
double** matrixgen(int order, double coefficients[order+2], double
    stepsize){
        double** outputmatrix = identity(order+1);
        for(int i=1; i<order; i++){
                outputmatrix[i][i+1] = stepsize;
        }
        outputmatrix[order][0] = -1/coefficients[0]*stepsize;
        for(int i=1; i<order+1; i++){
                outputmatrix[order][i] = (-coefficients[order+1-i]/
                    coefficients[0])*stepsize;
        }
        outputmatrix[order][order] += 1;
        return outputmatrix;}
```

```
double* recorddata(double lowerbound, double upperbound, int order,
    double coefficients[order+2], double initialconditions[order], double
    stepsize){
        double** vector_y = createMat(order+1,1);
        vector_y[0][0] = coefficients[order+1];
        for(int i=0;i<order;i++){
                vector_y[i+1][0] = initialconditions[i];
        }
        double** matrix = matrixgen(order, coefficients, stepsize);
        int no_datapoints = ((upperbound-lowerbound)/stepsize);
        double* yvalues = malloc(no_datapoints*sizeof(double));
        for(int i = 0; i<no_datapoints; i++){
                vector_y = Matmul(matrix,vector_y,order+1,order+1,1);
                yvalues[i] = vector_y[1][0];
        }
        return yvalues;
}
```

Python Code for Plotting

```
import ctypes
import numpy as np
import matplotlib.pyplot as plt

# Load the shared library
solver = ctypes.CDLL('./solver.so')

# Define the function signatures
solver.recorddata.restype = ctypes.POINTER(ctypes.c_double)
solver.recorddata.argtypes = [
    ctypes.c_double, # lowerbound
    ctypes.c_double, # upperbound
    ctypes.c_int, # order
    ctypes.POINTER(ctypes.c_double), # coefficients
    ctypes.POINTER(ctypes.c_double), # initialconditions
    ctypes.c_double # stepsize
]
```

```
# Define parameters
order = 2
lowerbound = 0.0
upperbound = 10.0
stepsize = 0.001
coefficients = np.array([1.0, 0.0, 0.0, 1.0], dtype=np.double)
initialconditions = np.array([0.0, 0.0], dtype=np.double)

# Calculate the number of data points
no_datapoints = int((upperbound - lowerbound) / stepsize)

# Call the C function
results_ptr = solver.recorddata(
    ctypes.c_double(lowerbound),
    ctypes.c_double(upperbound),
    ctypes.c_int(order),
    coefficients.ctypes.data_as(ctypes.POINTER(ctypes.c_double)),
    initialconditions.ctypes.data_as(ctypes.POINTER(ctypes.c_double)),
```

```
    ctypes.c_double(stepsize)
)
# Convert results back to a NumPy array
results = np.ctypeslib.as_array(results_ptr, shape=(no_datapoints,))
# Generate x-values for plotting
x_values = np.arange(lowerbound + stepsize, upperbound + stepsize,
    stepsize)
# Calculate the y-values for the function y = -1/2 * x^2
y_function = -0.5 * x_values**2
# Plot the data
plt.scatter(x_values, results, color='blue', s=1, label='Sim.')
plt.plot(x_values, y_function, color='red', label='Theory')
plt.xlabel('x')
plt.ylabel('y')
plt.legend()
plt.grid(True)
plt.savefig('../figs/fig.png')
plt.show()
```
